Computational physics

Theoretical physics

1. Discretized analytical calculations

2. Data treatment (ERN)

3. Algorithmic modeling.

→ Computational fluid dynamics

Navia - Stokes equations

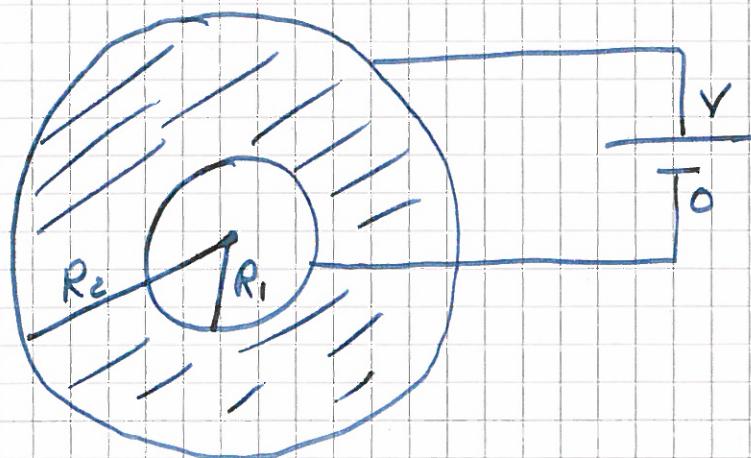

(discretization)
(numerical calculations.)

Two levels of description:

Nature → Continuous equation
 → discrete numerical models.

Typical problem:

Find electrical field inside an annulus with conducting inner and outer edges kept at fixed potentials.

Laplace equation:

$$\nabla^2 V = 0$$

Boundary conditions:

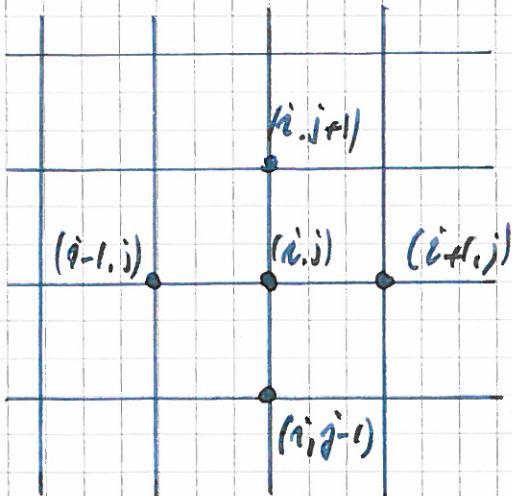

$$\left. \begin{aligned} V(\vec{R}_1) &= 0 \\ V(\vec{R}_2) &= V \end{aligned} \right\}$$

Continuous description

Discretization

$$\nabla^2 V(\vec{r}) \rightarrow$$

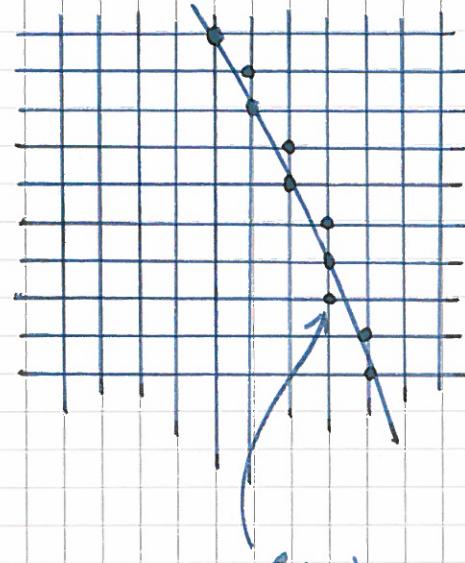

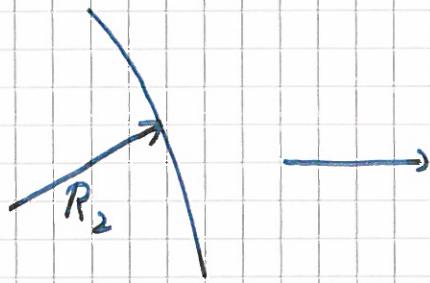

$$\boxed{\begin{aligned} V_{i,j+1} + V_{i,j-1} + \\ V_{i-1,j} + V_{i+1,j} - 4V_{i,j} = 0 \end{aligned}}$$

Discretized set of equations.

4

Boundary conditions:

$$(i, j) \quad V_{i,j} = V$$

$$\|(i, j)\| \approx R_2.$$

This results in a matrix equation:

$$V_{i,i+1} + V_{i,i-1} + V_{i-1,i} + V_{i+1,i} - 4V_{i,i} = 0$$

Whenever $V_{i,i}$ appearing here corresponds to a grid point on the boundary, move it to the right hand side.

\Rightarrow

$$\overset{\leftarrow}{A} \cdot \overset{\leftarrow}{V} = \overset{\leftarrow}{B}$$

↑

$$\begin{pmatrix} V_{1,1} \\ V_{1,2} \\ \vdots \end{pmatrix}$$

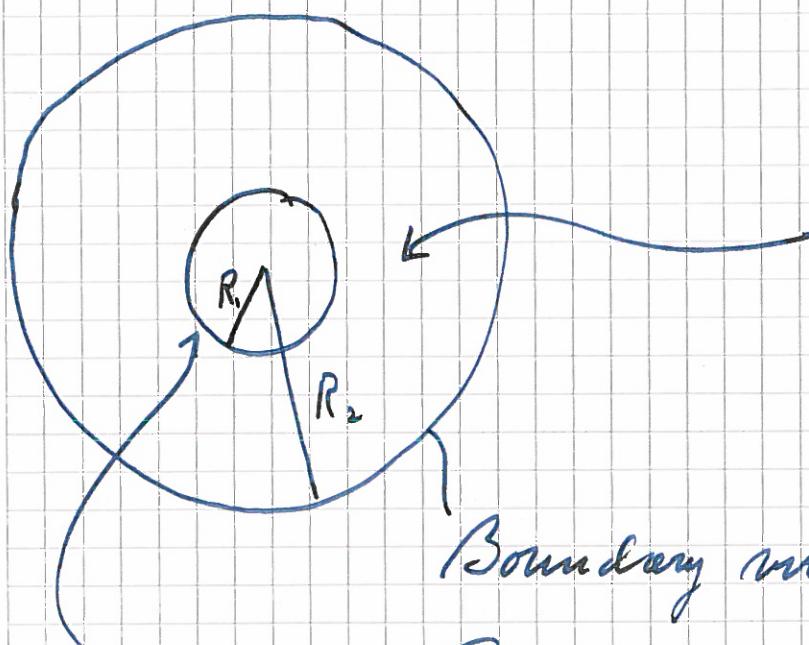

use a matrix solver \Rightarrow
problem solved.

We now consider the following
 related problem:

Diffusion-limited Aggregation.

DLA

Small (colloidal) particles diffusing
 in a liquid near a sticky wall.

Boundary with fixed concentration
 C .

Sticky boundary. Then the
concentration is zero.

(because all particles
near the boundary
gets absorbed by it.)

$$\begin{aligned} \nabla^2 C &= 0 \\ C(\vec{R}_1) &= 0 \\ C(\vec{R}_2) &= C \end{aligned} \quad \left. \right\}$$

7.

BUT, what if we take into account that the sticky boundary grows when the particles stick to it.

Simpler assumption:

Growth rate of surface is proportional to concentration gradient just outside.

If \dot{S} is the surface:

$$\boxed{\dot{S} \propto \nabla C}$$

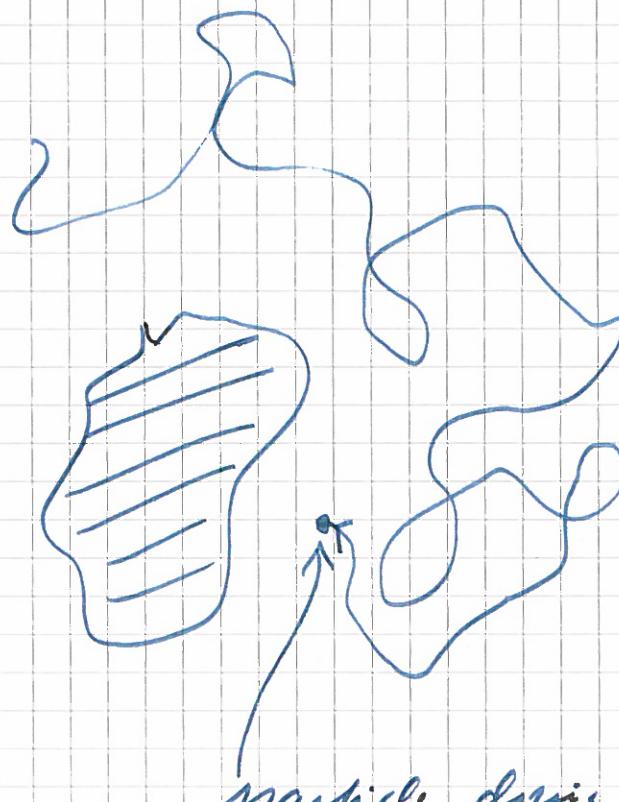

We are now dealing with a differential equation whose boundary conditions change with the solution.

It turns out that this problem is unsolvable on all scales:

The problem cannot be solved through solving a discretized differential equation.

This is where algorithmic modeling comes in:

Nature \rightarrow discrete models
I
no analytical intermediary.

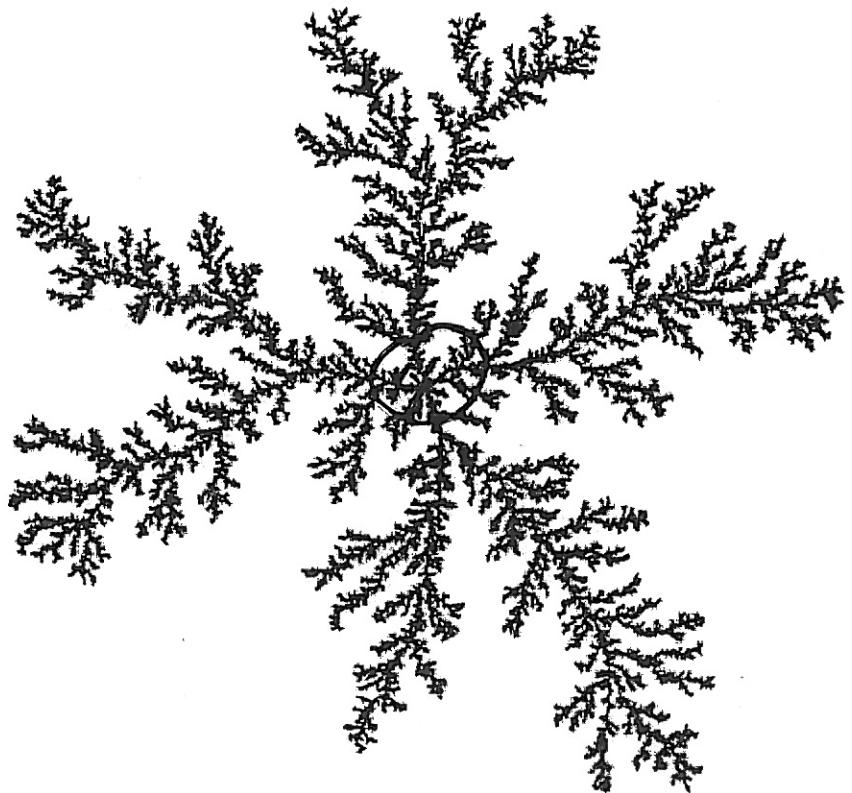

particle doing a random walk.
Where it hits the surface, it sticks.

This model renders a description that fits quantitatively with what is seen in nature.

Algorithmic modeling:

Model nature directly.

$$M \propto t^{\alpha} \quad \alpha \approx 1.2$$

DLA - diffusion-limited
aggregation.

Another example:

Bak-Sneppen model
for punctuated equilibrium.

Evolution (paleontology):

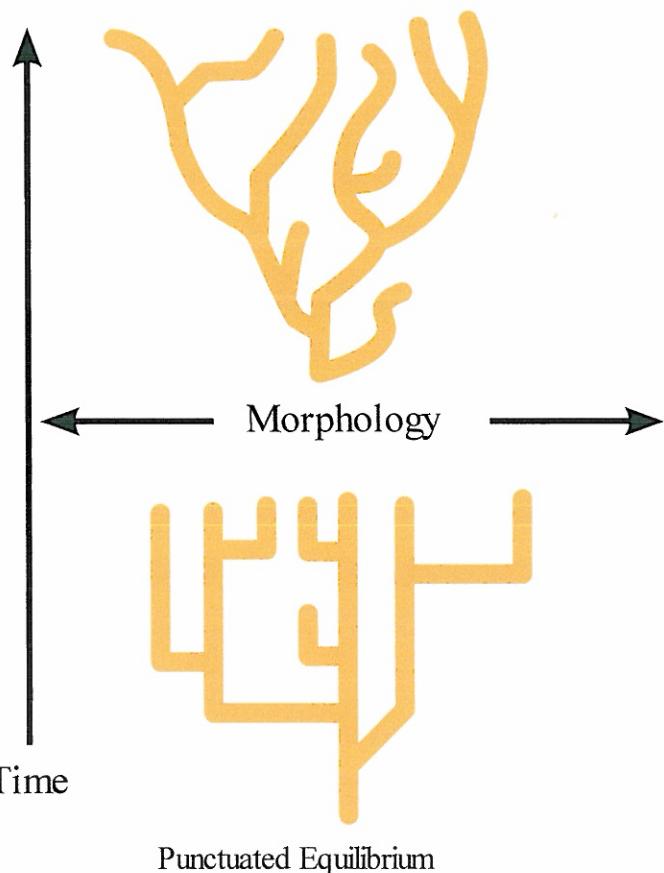

Evolution is not smooth
but proceeds in a
series of bursts.

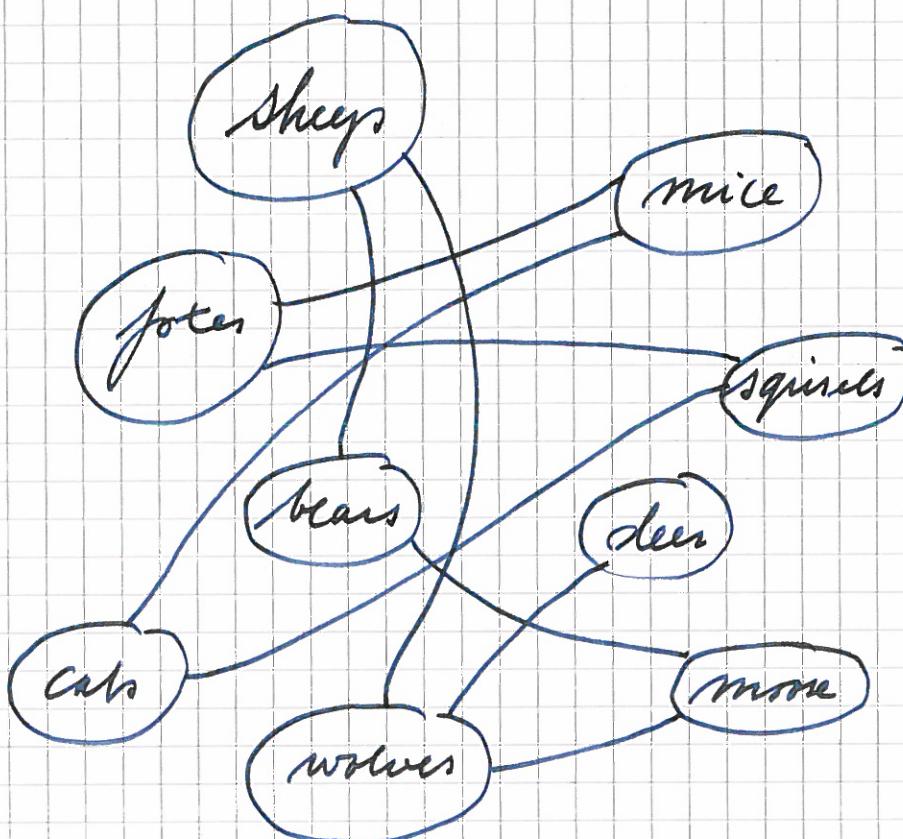

Are the bursts due to internal
instabilities or are external
catastrophes necessary?

(e.g. - extinction of
dinosaurs.)

Bak-Sneppen model:

Phyletic Gradualism

Each species is given a "fitness parameter."

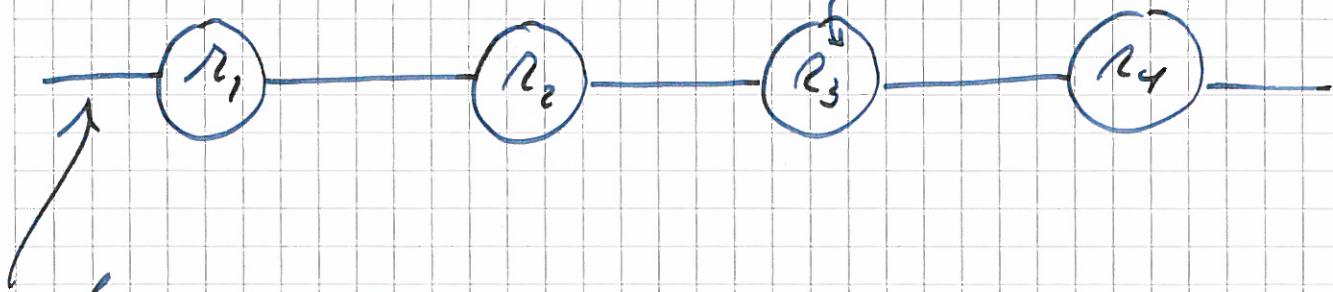

The higher, the better.

Species $i \rightarrow R_i$

↑
fitness parameter.

random #.

12

Simplify to a one-dimensional chain.

r_i - fitness parameter.

Extreme dynamics.

How to update the system:

① $r_s = \min_i r_i$, $r_{i(s)} = r_s$

② $r_{i(s)+1} \rightarrow$ new random $r_{i(s)+1}$

$r_{i(s)}$ \rightarrow new random $r_{i(s)}$

$r_{i(s)-1} \rightarrow$ new random $r_{i(s)-1}$

Some elementary stuff on what computers do with numbers.

(Vocabulary knowledge to be able to judge what the computer produces.)

How numbers are represented

Number → word

word

Consists of a string of bits.

May have length

32 or 64 or ...

We will assume 32-bit architecture.

This means that only a limited range of numbers may be represented with infinite precision.

Chemie, always an approximation.

$$x = \pm m \cdot 2^{e + e_0}$$

\pm	$e + e_0$	m (mantissa)
on 1	8 bits	23 bits

m is normalized: moved to the left as far as possible (and e is thus given).

Since the bit to the left of m is always 1, it is typically not stored.

This gives m a precision of 24 rather than 23 bits.

15

e_0 is a machine-specific integer
that is added to e to ensure
that $e_0 + e$ is always positive.

e_0 is called the bias.

Example :

With $e_0 = 151$, the number 0.25
is stored as :

$$0.25 = \frac{1}{4} = (1 \cdot 2^{22}) \cdot 2^{\frac{-24}{e}}$$

$$-24 + 151 = 127$$

1	2	3	4	5	6	7	8	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23
1	1	0	0	1	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

$\underbrace{11}_{e_0 + e}$ $\underbrace{00110000000000000000000000000000}_m$

$$151 = 1 \cdot 128 + 0 \cdot 64 + 0 \cdot 32 + 1 \cdot 16 + 0 \cdot 8$$

$$127 = 64 + 32 + 16 + 8 + 4 + 2 + 1 + 1 \cdot 4 + 1 \cdot 2 + 1 \cdot 1$$

$$= 10010111$$

\uparrow Binary.

How the computer performs
elementary operations.

Addition

$$x_1 + x_2$$

$$\left. \begin{array}{l} x_1 = \pm m_1 \cdot 2^{e_1 + e_0} \\ x_2 = \pm m_2 \cdot 2^{e_2 + e_0} \end{array} \right\} \text{assume } e_1 \leq e_2.$$

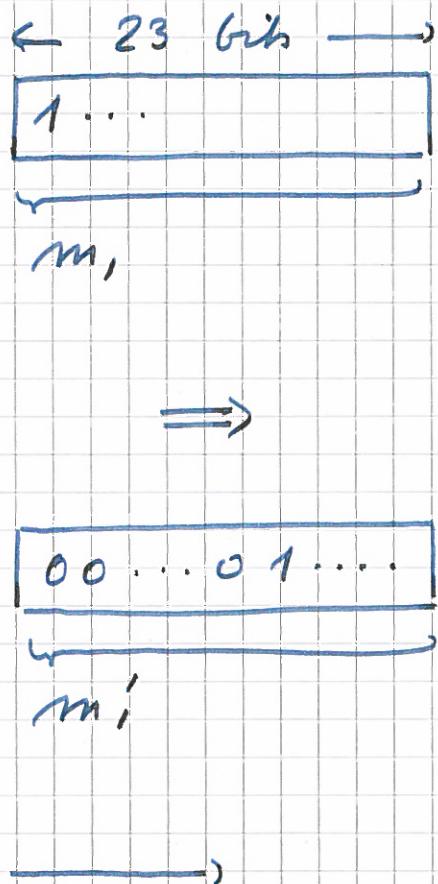

The exponent and machine of
 x_1 is adjusted so that its new
exponent e_1' is equal to that of
 x_2 :

$$x_1 = \pm m_1 \cdot 2^{e_1 + e_0} = m_1' \cdot 2^{e_2 + e_0}$$

$$m_1' = m_1 \cdot 2^{e_1 - e_2}$$

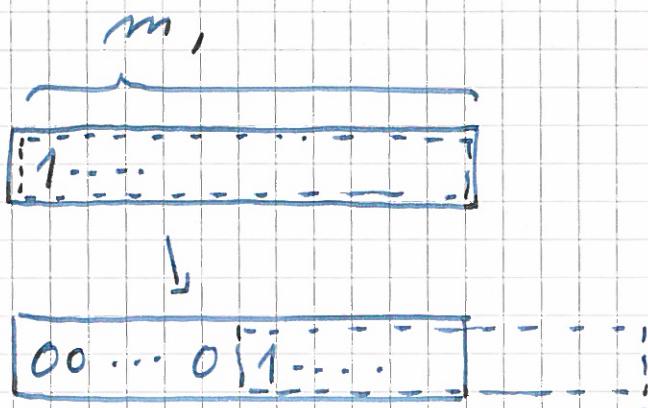

The addition operation is then performed as:

$$X_1 + X_2 = [(\pm m_1) + (\pm m_2)] e^{e_2 + e_0}$$

The adjustment has pushed the mantissa to the right.

This results in loss of the less significant bits.

This is lost.

This is roundoff error.

Definition of machine precision:

Smallest number that can be added to 1 giving a result different from 1.

19

Example :

$$2^{-22} = 2.38 \cdot 10^{-7}$$

$$\begin{array}{r} + \\ 129 \\ \hline 100 \dots \\ \hline 000 \end{array}$$

$$+ \begin{array}{r} + \\ 107 \\ \hline 100 \end{array} \dots \begin{array}{r} 000 \\ 2^{12} \end{array}$$

2

$$\begin{array}{r} + \\ 129 \\ \hline 100 \dots \\ \hline 000 \end{array}$$

$$+ \quad + \quad 129 \quad 100 \dots \quad 001 \quad 2^{-\infty}$$

$$\text{But } 1 + 2^{-23} = 1$$

Subtraction works using the
same principles.

However, the subtraction of two almost equal numbers is a dangerous operation.

(Since division corresponds to subtraction of logarithms, the same is true for this case.)

Example:

$$2^{23} - 1$$

$$\begin{array}{r} + \\ \hline 35 & 11\dots & 11 \end{array}$$

$$\begin{array}{r} - \\ \hline + & 35 & 11\dots & 110 \end{array}$$

$$= \begin{array}{r} + \\ \hline 35 & 00\dots & 001 \end{array}$$

$$= \begin{array}{r} + \\ \hline 73 & 10\dots & 0000 \end{array}$$

Filled with zeros:
50% accuracy.
